HOW TO READ

Delay = expected warehouse arrival – clock. Same ETA, two clocks.

Blue = SAP Pl.arr.date. Red = Actual GI date + 72 calendar days.

One point per GI date = mean of deliveries that left DE that day (not SO-weighted).

Dropped 1 SO at -272d and 1 Sep-2025 row without Pl.arr. Source n=1395 SO / 450 deliveries.

WHAT THE GAP MEANS

Pl.arr delay averages 3.2d higher than AGI+72. Planned arrival is ~3 days tighter than the 72-day rule.

Only 12 deliveries beat Pl.arr.date. None beat AGI+72 (floor +1d).

June GI: Pl.arr 26.9d / AGI+72 22.7d. August: 10.1 / 7.6.

The two lines move together. The clock choice changes the level, not the shape.

DO NOT READ AUGUST AS RECOVERY

August GI warehouse dates are still ETAs. Less delay can mean less time for the ETA to slip.

Heavy GI days (n≥25 labelled) still sit on the same two-clock gap.

This is warehouse-ETA delay, not HAM→SHA sailing days, and not door-to-Dushan.

Factory 55d sailing LT and AGI+72 are different clocks — do not swap them.
